

Shape-Outside CSS Feature Demo

1. shape-outside: url()

Text flows around the image's alpha channel. The shape-image-threshold controls which pixels define the boundary. This creates natural text wrapping around irregular shapes rather than rectangular bounding boxes.

2. shape-outside: circle()

The circle() function creates a circular text wrap area. Text flows smoothly around the curved boundary. Perfect for portraits, logos, or any circular imagery in your layouts.

3. shape-outside: polygon()

Polygon() defines custom vertices for any shape. This diamond uses four points: top, right, bottom, left. You can create any polygonal shape by specifying coordinate pairs.

4. shape-outside: border-box

Border-box uses the element's border-box as the shape, including border-radius. This creates rounded shapes without images. Combined with border-radius, you get pill or rounded rectangle shapes.

5. Dual Float Layout

Text flows between two floated shapes simultaneously. This creates decorative margins or frames around content. Both elements use shape-outside: border-box with border-radius to create the pill shapes.

6. Tight Wrap (Centered Image)

This technique places a centered image with text flowing around both sides. The visible image floats right in column one with `shape-outside: circle()`. Two overlapping columns wider than 50% each create the effect. The negative margin on column two causes them to overlap precisely at the image location.

An invisible spacer in column two mirrors the shape boundary. Text in each column flows around its respective float, creating the illusion of a single centered image. This is perfect for hero images, product showcases, author photos, or any featured visual content in your layouts.
